Definition

A set $\Gamma^d \subset \mathbb{R}^N$ is called a $d$-dimensional simple polytope if it is a compact convex subset of dimension $d$, with affine support $E^d \subset \mathbb{R}^N$, for which there exist a family of affine functions $\{f_i : E^d \to \mathbb{R}\}_{i \in I}$ such that

(a) $\Gamma^d = \bigcap_{i \in I} f_i^{-1}([0, +\infty[)$. 

(b) $\Gamma^d \cap f_i^{-1}(0) \neq \emptyset \quad \forall i \in I$. 

(c) Given $J \subseteq I$ such that $\Gamma^d \cap (\bigcap_{j \in J} f_j^{-1}(0)) \neq \emptyset$, the linear 1-forms $df_j$ are linearly independent at every point $p \in \bigcap_{j \in J} f_j^{-1}(0)$. 

- $V$ set vertices $v$,
- $E$ set of edges $\gamma$ and $E_v$ set of edges containing $v$.
- $F$ set of faces $\sigma$ and $F_v$ set of faces containing $v$.
- the set of corners
  \[ C := \{ (v, \gamma, \sigma) \in V \times E \times F : \gamma \cap \sigma = \{v\} \}. \]

**Figure:** A corner $(v, \gamma, \sigma)$ in a three dimensional polytope.
By (c) of Definition 1 at any given vertex $\nu$, the co-vectors $(d f_i)_\nu$ are linearly independent. So in a small enough neighborhood of $\nu$ the functions $\{f_\sigma\}_{\sigma \in F_\nu}$ can be used as a system of coordinates.
Example: $\Gamma^2 \subset \mathbb{R}^2$ defined by

\[ f_1(x) = x_1, \quad f_2(x) = x_2, \quad f_3(x) = 1 - x_1 - x_2 \]
\[ \mathcal{A}(\Gamma^d) := \text{the space of functions defined on } \Gamma^d \text{ that can be extended analytically to a neighborhood of } \Gamma^d, \]

\[ \mathcal{X}(\Gamma^d) := \text{the space of vector fields } X, \text{ defined on } \Gamma^d, \text{ that have an analytic extension to a neighborhood of } \Gamma^d \text{ and such that } X \text{ is tangent to every } r\text{-dimensional face of } \Gamma^d, \text{ for all } 0 \leq r \leq d. \]
**Figure:** The local, $P_{lo}$, and global, $P_{gl}$, Poincaré maps along a heteroclinic orbit.

The asymptotic linearization of $P_{gl}$ will be identity.
$N_v := \{ p \in \Gamma^d : 0 \leq x_j(p) \leq 1 \text{ for } 1 \leq j \leq d \}$

where $(x_1, \ldots, x_d)$ is a system of affine coordinates around $v$ which assigns coordinates $(0, \ldots, 0)$ to $v$ and such that the hyperplanes $x_j = 0$ are precisely the facets of the polytope through $v$. 
Figure: Tubular neighborhoods along the edges in a two dimensional polytope
We blow up this tubular neighborhood by a rescaling change of coordinates. The rescaling change of coordinates $\psi^X_\epsilon$ takes points in $N_v$ to points in the sector

$$\Pi_v := \{(y_\sigma)_{\sigma \in F} \in \mathbb{R}^{|F|}_+ \text{ s.t. } y_\sigma = 0 \text{ when } \sigma \notin F_v \}.$$ 

If $F_v = \{\sigma_1, \ldots, \sigma_d\}$, the map $\psi^X_\epsilon$, generically, is defined on the neighborhood $N_v$ by

$$\psi^X_\epsilon(q) := (-\epsilon^2 \log x_1(q), \ldots, -\epsilon^2 \log x_d(q), 0, \ldots, 0).$$

Outline
Asymptotic Poincaré Map
Hamiltonian Polymatrix replicators
Hamiltonian Asymptotic Poincare map
example
\( X \in \mathfrak{X}(\Gamma^d) \) is tangent to a given face \( \sigma := \{ q \in \Gamma^d, f(q) = 0 \} \), then

\[
df_\sigma(X) = 0 \Rightarrow \exists H_\sigma \in \mathcal{A}(\Gamma^d) \text{ s.t. } df_\sigma(X) = (F_\sigma)^{\nu(X,\sigma)} H_\sigma
\]

For a smooth vector field \( X \), the order \( \nu(X, \nu, \sigma) \) at a corner \((\nu, \sigma)\) is the minimum integer \( k \geq 1 \) such that

\[(df_\sigma)_\nu(D^kX)_\nu \neq 0. \]

The order of \( \sigma \) is defined as

\[
\nu(X, \sigma) := \min_{\nu} \{ \nu(X, \nu, \sigma) : \sigma \in F_\nu \}.
\]
Order function: \( \nu : \mathcal{X}(\Gamma^d) \times F \rightarrow \{1, 2, 3, \ldots\} \).

**Definition**

The *skeleton character* of \( X \in \mathcal{X}(\Gamma^d) \) is defined to be the family \( \chi := (\chi^v_{\sigma})_{(v, \sigma) \in V \times F} \) where

\[
\chi^v_{\sigma} := \begin{cases} 
-H_{\sigma}(v) & \sigma \in F_v \\
0 & \text{otherwise} 
\end{cases},
\]

while the *skeleton character* at \( v \in V \), is \( \chi^v := (\chi^v_{\sigma})_{\sigma \in F} \).
Consider a corner \((v, \gamma, \sigma)\), if \(\nu(X, \sigma) = 1\) then \(\chi^v_\sigma\) is simply minus the eigenvalue of the linearization of \(X\) at equilibrium \(v\) along its eigenvector \(\gamma\).
Consider a corner \((v, \gamma, \sigma)\), if \(\nu(X, \sigma) = 1\) then \(\chi_\sigma^v\) is simply minus the eigenvalue of the linearization of \(X\) at equilibrium \(\nu\) along its eigenvector \(\gamma\).
Note that $\chi^v$ is tangent to
\[ \Pi_v := \{(y_\sigma)_{\sigma \in F} \in \mathbb{R}^{|F|} \text{ s.t. } y_\sigma = 0 \text{ when } \sigma \notin F_v\}. \]

**Definition**

- The dual cone of the polytope $\Gamma^d$ is
  \[ \mathcal{C}^*(\Gamma^d) := \bigcup_{v \in V} \Pi_v \subset \mathbb{R}^{|F|}. \]
- Given $X \in \mathcal{X}(\Gamma^d)$, the family $\chi := \{\chi_v\}_{v \in V}$ is called the skeleton vector field associated to $X$. 
For every $n = 1, 2, \ldots$, define $h_n : (0, \infty) \rightarrow \mathbb{R}$ to be

$$h_1(x) = -\log x \quad \text{and} \quad h_n(x) = -\frac{1}{n-1} \left( 1 - \frac{1}{x^{n-1}} \right) \quad n \geq 2.$$  

(1)

Remark

This family can also be characterized by the properties:

$h'_n(x) = -x^{-n}$, $h_n(0) = +\infty$ and $h_n(1) = 0$, which prove that the function $h_n : ]0, 1] \rightarrow [0, +\infty[$ is a diffeomorphism.
Definition

Given a vector field $X \in \mathcal{X}(\Gamma^d)$ with $n = |F|$ facets we define the $\epsilon$-rescaling coordinate system $\psi^X_\epsilon : N_{\Gamma^d} \setminus \partial \Gamma^d \to \mathbb{R}^n$ which maps $q \in N_{\Gamma^d}$ to $y := (y_{\sigma_1}, \ldots, y_{\sigma_n})$ where

- If $q \in N_\nu$ for some vertex $\nu$:
  
  $y_{\sigma_i} = \begin{cases} 
  \epsilon^2 h_\nu(X,\sigma_i)(f_\sigma(q)) & \text{if } \sigma \in F_\nu \\
  0 & \text{if } \sigma \notin F_\nu
  \end{cases}$

- If $q \in N_\gamma$ for some edge $\gamma$:
  
  $y_{\sigma_i} = \begin{cases} 
  \epsilon^2 h_\nu(X,\sigma_i)(f_\sigma(q)) & \text{if } \gamma \subset \sigma \\
  0 & \text{if } \gamma \not\subset \sigma
  \end{cases}$
Definition

Suppose we are given a family of functions, or mappings, $F_\epsilon$ with varying domains $\mathcal{U}_\epsilon$. Let $F$ be another function with domain $\mathcal{U}$. Assume that all these functions have the same target and source spaces, which are assumed to be linear spaces. We will say that $\lim_{\epsilon \to 0^+} F_\epsilon = F$ in the $C^\infty$ topology, to mean that:

1. **domain convergence**: for every compact subset $K \subseteq \mathcal{U}$, we have $K \subseteq \mathcal{U}_\epsilon$ for all small enough $\epsilon > 0$, and

2. **derivative uniform convergence on compacts**: for every $k \in \mathbb{N}$

$$\lim_{\epsilon \to 0^+} \sup_{u \in K} \left| D^i [F_\epsilon(u) - F(u)] \right| = 0.$$
For a given vertex \( v \in V \) we define

\[
\Pi_v(\varepsilon) := \{ y \in \Pi_v : y_{\sigma} \geq \varepsilon \text{ for all } \sigma \in F_v \}
\]  

(2)

Lemma

The push-forward of \( X \) by \( \psi^X_{v,\varepsilon} \) is

\[
(\psi^X_{v,\varepsilon})^* X = \varepsilon^2 \tilde{X}^\varepsilon_v,
\]

where \( \tilde{X}^\varepsilon_v := (-H_{\sigma} ((\psi^X_{v,\varepsilon})^{-1}(y))_{\sigma \in F_v} \). Furthermore, the following limit holds in the \( C^\infty \) topology

\[
\lim_{\varepsilon \to 0} (\tilde{X}^\varepsilon_v)|_{\Pi_v(\varepsilon)} = \chi^v.
\]
Let $X \in \mathcal{X}(\Gamma^n)$ and $\chi$ be its skeleton vector field.

**Definition**

The vertex $v$ is called

- $\chi$-attractive if $\chi^v \in \Pi_v$
- $\chi$-repelling if $-\chi^v \in \Pi_v$
- of saddle type otherwise.

Asymptotic Poincare maps for Polytopes
Definition

The edge $\gamma$ is with end corners $(v_i, \sigma_i)$ and $(v_j, \sigma_j)$ is called $\chi$-defined if either $\chi^v_{\sigma_i} \chi^v_{\sigma_j} \neq 0$ or else $\chi^v_{\sigma_i} = \chi^v_{\sigma_j} = 0$. Moreover, we say that $\gamma$ is

- a flowing-edge if $\chi^v_{\sigma_i} \chi^v_{\sigma_j} < 0$,
- a neutral edge if $\chi^v_{\sigma_i} = \chi^v_{\sigma_j} = 0$,
- an attracting edge if $\chi^v_{\sigma_i} < 0$ and $\chi^v_{\sigma_j} < 0$,
- a repelling edge if $\chi^v_{\sigma_i} > 0$ and $\chi^v_{\sigma_j} > 0$,
- a $\chi$-undefined if non of the above happens.

For flowing-edges we write $v_i \xrightarrow{\gamma} v_j$ whenever $\chi^v_{\sigma_i} < 0$ and $\chi^v_{\sigma_j} > 0$. The vertex $v_i := s(\gamma)$ called source and $v_j := t(\gamma)$ called target.
The flowing edge $v_2 \xrightarrow{\gamma} v_1$
For a given vertex $v_i$ of saddle type together with an incoming flowing-edge $(v_{i-1}, \sigma^s_j) \xrightarrow{\gamma_j} (v_i, \sigma^t_j)$ and an outgoing flowing-edges $(v_i, \sigma^s_{j+1}) \xrightarrow{\gamma_{j+1}} (v_{i+1}, \sigma^t_{j+1})$, let

$$L_{\gamma_j, \gamma_{j+1}}(y) := \left( \begin{array}{c} y_\sigma - \frac{\chi^{v_i}_\sigma}{\chi^{v_i}_s} y_{\sigma^s_{j+1}} \\ \chi^{v_i}_s \chi^{v_i}_{\sigma^s_{j+1}} \end{array} \right)_{\sigma \in F}$$

(3)

with the domain $\pi_{\gamma_j, \gamma_{j+1}} := \{ y \mid y_\sigma - \frac{\chi^{v_i}_\sigma}{\chi^{v_i}_s} y_{\sigma^s_{j+1}} > 0 \}$.

\[ y_2 \]
\[ y_1 \]

\[ L^\chi_{\gamma,\gamma'}(x) \]
Definition

A sequence of edges $\xi = (\gamma_0, \gamma_1, \ldots, \gamma_m)$ is called a $\chi$-path if

1. $\gamma_j$ is flowing, for all $j = 0, 1, \ldots, m$,
2. $t(\gamma_{j-1}) = s(\gamma_j)$, for all $j = 1, \ldots, m$.

The $\chi$-path $\xi$ is called a cycle when $\gamma_0 = \gamma_m$. The integer $m$ is called the length of the path.
Definition

Given a $\chi$-path $\xi = (\gamma_0, \gamma_1, \ldots, \gamma_m)$, we define the *skeleton Poincaré map of $\chi$ along $\xi$* to be the mapping $\pi_\xi : \Pi_\xi \to \Pi_{\gamma_m}$

$$\pi_\xi := L_{\gamma_{m-1}, \gamma_m} \circ \cdots \circ L_{\gamma_0, \gamma_1} ,$$

Evolutionary Game Theory

EGT originated from the work of:

John Maynard Smith and George R. Price

who applied the theory of strategic games developed by:

John von Neumann and Oskar Morgenstern

to evolution problems in Biology.

Unlike Game theory which is more concentrated on mathematical modeling, EGT investigates the dynamical processes of biological populations.
Let \( n = (n_1, \ldots, n_p) \) where \( p \) and \( n_i \) are positive integers and set \( n = n_1 = \ldots + n_p \). We denote

\[
\mathbb{R}^n \ni x = (x^\alpha)_\alpha, \text{ where } x^\alpha \in \mathbb{R}^{n_\alpha}, \alpha = 1, \ldots, p. \\
i \in \alpha, \text{ if and only if } n_1 + \ldots + n_{\alpha-1} < i \leq n_1 + \ldots + n_\alpha.
\]
Consider a block matrix

$$A = \begin{bmatrix} A^{\alpha,\beta} \end{bmatrix}_{\alpha,\beta},$$

where $\alpha, \beta = 1, \ldots, p$ and each block $A^{\alpha,\beta} = \begin{bmatrix} a^{\alpha,\beta}_{ij} \end{bmatrix}_{ij}$ is a $n_\alpha \times n_\beta$ real matrix.
We define the polymatrix replicator equation associated to \( A \), on the prism
\[
\Gamma_n = \Delta^{n_1-1} \times \ldots \times \Delta^{n_p-1},
\]
where \( \Delta^{n_\alpha-1} = \{ x \in \mathbb{R}^{n_\alpha}_+ \mid \sum_{i=1}^{n_\alpha} x_i = 1 \} \), by
\[
\dot{x}_i^\alpha = x_i^\alpha \left( (A x)_i - \sum_{\beta=1}^{p} (x_\alpha)^t A^\alpha,\beta x_\beta \right) \quad \forall \ i \in \alpha, \ \alpha \in \{1, \ldots, p\}, \quad (4)
\]
We will denote \( X_{(n,A)} = (\dot{x}_1, \ldots, \dot{x}_n) \).
Remark

\( X_{(n,A)} \) preserves \( \Gamma_n \) and all its faces. Restriction of \( X_{(n,A)} \) to any face is also a Polymatrix Replicator equation.

Polymatrix replicator equation is a mathematical model for polymatrix games and generalizes

1) Replicator equations when \( p = 1 \),

2) Asymmetric Replicator equations (Bimatrix Games) when \( p = 2 \) and

\[
A = \begin{bmatrix}
0 & A_{12} \\
A_{21} & 0
\end{bmatrix}
\]
Proposition (Equilibria)

A point $q \in \Gamma_{n}^n$ is an equilibrium of $X_{n,A}$ if $(Aq)_i = (Aq)_j$, for all $\alpha = 1, \ldots, p$ and every $i, j \in \alpha$. Moreover, if $q \in \Gamma_{n}^n$ is an equilibrium point then $(Aq)_i = (Aq)_j$, for all $\alpha = 1, \ldots, p$ and every $i, j \in \alpha$.

Definition

A formal equilibrium of a polymatrix game $G = (n, A)$ is any vector $q \in \mathbb{R}^n$ such that

(a) $(Aq)_i = (Aq)_j$ for all $i, j \in \alpha$, and all $\alpha = 1, \ldots, p$,
(b) $\sum_{j \in \alpha} q_j = 1$ for all $\alpha = 1, \ldots, p$. 
Hamiltonian Replicator Equations

Notation:

\[ \mathbb{1}_n := \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & \ddots & \\ & & & 1 \end{pmatrix} \in \mathbb{R}^n \]

and given \( x \in \mathbb{R}^n \), we denote by \( D_x \) the \( n \times n \) diagonal matrix \( D_x = \text{diag}(x_i)_i \).

For each \( \alpha \in \{1, \ldots, p\} \) we define the \( n_\alpha \times n_\alpha \) matrix

\[ T_x^\alpha := x^\alpha \mathbb{1}^t - I, \]

and set \( T_x \) to be the \( n \times n \) block diagonal matrix \( T_x = \text{diag}(T_x^\alpha)_\alpha \).
Definition

Given a polymatrix game $G = (n, A)$, we define the matrix valued mapping $\pi_A : \mathbb{R}^n \rightarrow \text{Mat}_{n \times n}(\mathbb{R})$

$$\pi_A(x) := (-1)^T x D_x A D_x T_x^t.$$  (5)

Notice that $\pi_A(x)$ is a skew symmetric matrix valued map whenever $A$ is a skew symmetric matrix.
Proposition

Given $A \in \text{Mat}_{n\times n}(\mathbb{R})$, assume there exists a formal equilibrium $q \in \mathbb{R}^n$ of $G = (n, A)$. Then, setting $H(x) = \sum_{i=1}^{n} q_i \log x_i$,

$$X_{(n,A)}(x) = \pi_A(x) \, d_x H \quad \text{for every} \quad x \in \Gamma_n.$$

In fact the above equation holds for every point in the affine space generated by $\Gamma_n$. 
Theorem

When $A$ is anti-symmetric, $\pi_A$ defines a Poisson structure on $\Gamma_n$. 
Proof

We define diffeomorphism \( \phi : \mathbb{R}^{n-p} \to \Gamma^p_n \), where
\[ \phi(u^{\alpha}) := (\phi^{\alpha}(u^{\alpha}))_{\alpha} \text{ for } \alpha = 1, \ldots, p \text{ and each component } \phi^{\alpha} : \mathbb{R}^{n_{\alpha}-1} \to (\Delta^{n_{\alpha}-1})^\circ \]is the map defined by

\[
\phi^{\alpha}(u^{\alpha}) := \left( \frac{e^{u^{\alpha}_1}}{1 + \sum_{i=1}^{n_{\alpha}-1} e^{u^{\alpha}_i}}, \ldots, \frac{e^{u^{\alpha}_{n_{\alpha}-1}}}{1 + \sum_{i=1}^{n_{\alpha}-1} e^{u^{\alpha}_i}}, \frac{1}{1 + \sum_{i=1}^{n_{\alpha}-1} e^{u^{\alpha}_i}} \right) \quad \text{(6)}
\]

Where \( u \in \mathbb{R}^{n-p} = \mathbb{R}^{n_1-1} \times \ldots \times \mathbb{R}^{n_p-1} \) is considered as \( u = (u^{\alpha})_{\alpha} \) with \( u^{\alpha} := (u^{\alpha}_1, \ldots, u^{\alpha}_{n_{\alpha}-1}) \).
For every $u \in \mathbb{R}^{n-p}$ and $x = \phi(u)$, we have

$$(d_u \phi)B(d_u \phi)^t = (-1) T_x D_x A D_x T_x^t = \pi_A(x),$$

(7)

where $d_u \phi$ denotes the jacobian of $\phi$ at point $u$ and $B := (-1) E A E^t$ where $E$ is the block diagonal matrix $E := \text{diag}(E_1, \ldots, E_p)$ in which $E_\alpha$ is the $(n_\alpha - 1) \times n_\alpha$ block matrix defined as follows

$$E_\alpha := \begin{bmatrix} -1 & 0 & \cdots & 0 & 1 \\ 0 & -1 & \cdots & 0 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & -1 & 1 \end{bmatrix}, \quad \alpha = 1, \ldots, p$$

(8)
The condition of $A$ being anti-symmetric can be relaxed a bit in the sense that:

If there exist a diagonal matrix $D$ and an anti-symmetric matrix $A_0$ such that $A = A_0 D$, Then the polymatrix replicator $X_{A,n}$ is Hamiltonian with respect to Poisson structure $\pi_{A_0}$ having $\tilde{H} = H \circ D$ as its Hamiltonian.
In a recent work, which will be on arxiv soon, we extended this result using Dirac\big-isotropic structures, i.e. introduced Hamiltonian polymatrix replicators with Dirac\big-isotropic structures as underlying geometry.

\[
\text{Dirac} : \quad L = L^\perp \\
\text{big-isotropic} : \quad L \subset L^\perp
\]
In the context of Poisson geometry:

**Generic Hamiltonian Polymatrix replicators**

\[ \text{Hamiltonian skeleton character} \]
Let

\[(A_1)_i^\alpha := \sum_{\beta \neq \alpha} (A^{\alpha, \beta} x^\beta)_i + \sum_{k \neq i} a_{i k}^{\alpha, \alpha} x_k^\alpha - \sum_{\beta \neq \alpha} \sum_{k \neq i} x_k^\alpha (A^{\alpha, \beta} x^\beta)_k - \sum_{k, l \neq i} x_k^\alpha a_{k, l}^{\alpha, \alpha} x_l^\alpha, \tag{9}\]

\[(A_2)_i^\alpha := a_{i, i}^{\alpha, \alpha} - \sum_{\beta \neq \alpha} (A^{\alpha, \beta} x^\beta)_i - \sum_{k \neq i} (a_{i, k}^{\alpha, \alpha} + a_{k, i}^{\alpha, \alpha}) x_k, \tag{10}\]
Proposition

Let $X_A$ be a polymatrix replicator defined on $\Gamma_n$. Then for every face $\sigma_i^\alpha \in F$

$$\nu(X_A, \sigma_i^\alpha) = \begin{cases} 
3 & \text{if the polynomials (9) and (10) vanish} \\
2 & \text{if the polynomial (9) vanishes} \\
1 & \text{otherwise,}
\end{cases}$$
By generic, I mean Hamiltonian polymatrix replicators where

$$\nu(X_A, \sigma_i^\alpha) = 1 \quad \text{for all faces}$$
Let $(M, \pi)$ be a Poisson manifold and denote by $\mathcal{F}$ its symplectic foliation. A submanifold $N \subset M$ is called a *Poisson-Dirac submanifold* if $N$ is a poisson manifold and

1. The symplectic foliation of $N$ is $\mathcal{F}_N = N \cap \mathcal{F}$.

2. For every leaf $L \in \mathcal{F}$, $L \cap N$ is a symplectic submanifold of $L$. 
Also, the rank of the Poisson-Dirac submanifold $N$ at point $x \in N$ is defined to be the number

$$(\text{rank } N)_x = \dim(T_x N^\circ \cap \text{Ker}\pi_x^\#),$$

where $\pi^\# : T^* M \to TM$ is the vector bundle map defined by $\xi \to \pi(\xi, \cdot)$ and

$$T_x N^\circ := \{\xi \in T^*_x M | \xi(v) = 0 \ \forall v \in T_x N\}$$

is the annihilator of $T_x N$ in $T^*_x M$. 
Since a Poisson manifold is determined completely by its symplectic foliation, every Poisson-Dirac submanifold $N$ of a Poisson manifold $M$ has a unique Poisson structure that is been induced by the Poisson structure of $M$. In the language of Poisson brackets, one can compute the induced Poisson structure $\pi_N$ as follows

$$\pi_N(df_1, df_2) = \{f_1, f_2\}_N = \{\tilde{f}_1, \tilde{f}_2\}|_N,$$

(11)

where $\tilde{f}_i$ is an extension of $f_i \in C^\infty(N)$ to $M$ such that $df_i|_{\pi^\ast(TN)} = 0$ for $i = 1, 2$. 
Definition

A submanifold $N$ of $(M, \pi)$ is called \textit{pointwise Poisson-Dirac} submanifold if and only if for every $x \in N$,

$$T_x N \cap \pi^\#(T_x N^\circ) = \{0\}.$$ 

Lemma

A \textit{pointwise Poisson-Dirac} submanifold $N$ is Poisson-Dirac if the rank of $N$ is constant all over $N$. 

Hassan Alishah  \hspace{1cm} Assymptotic Poincare maps for Polytopes
Consider a Hamiltonian $H$ on the $m$-dimensional Poisson manifold $(M, \pi)$ and fix a point $x_0 \in M$ such that $X_H(x) \neq 0$. Consider a $(m - 2)$ dimensional transversal section to $X_H$ at point $x_0$

$$\Sigma \subset H^{-1}(e_1) \cap U,$$

where $H(x_0) = e_1$. 
Let $dG$ be the 1–form in which $\{d_x H, d_x G\}$ is a basis for $T_x \Sigma^\circ$ (shrink $U$ if necessary). Then

$$T_{\Sigma} M = T\Sigma \oplus \mathbb{R}X_H \oplus \mathbb{R}X_G.$$  

**(12)**

**Lemma**

*Every transversal section $\Sigma$ defined as above is a Poisson-Dirac submanifold of $M$.***
For a fixed time $t_0$, let $x_1 = \phi_H(t_0, x_0)$, where $\phi_H$ is the flow of the Hamiltonian vector field $X_H$, and $\Sigma_0, \Sigma_1$ are transversal sections at $x_0$ and $x_1$, respectively. As usual, a Poincaré map $P = \phi_H(\tau(x), x)$ can be defined from an appropriate neighbourhood of $x_0$ in $\Sigma_0$ to a neighborhood of $x_1$ in $\Sigma_1$. 
Proposition

The Poincaré map $P : (\Sigma_0, \pi_{\Sigma_0}) \rightarrow (\Sigma_1, \pi_{\Sigma_1})$, where $\pi_{\Sigma_i} \ i = 0, 1$ are the induced Poisson structures defined at (11), is a Poisson map.
The payoff matrix $A$ being anti-symmetric, the map $P_{lo}$ can be defined from a co-dimension 2 section $\Sigma_0$ to a codimension 2 section $\Sigma_1$ and it is a Poisson map.
If all the faces of $\Gamma_n$ has degree one, the subspace of the gray line associated to $\Sigma_0$ inherits a Poisson structure.
And the asymptotic Poincare map is a time one map of a Hamiltonian flow i.e. the Hamiltonian character of the dynamics is inherited by the asymptotic Poincare map.
This simplifies life by dropping the dimension to the dimension of the symplectic leaves. We found examples of Hamiltonian vector field where the study of the asymptotic flow reveals existence of chaotic behavior.
Let $\rho = 1$ and $n = (5)$ and

$$A = \begin{bmatrix} 0 & -2 & 2 & -2 & 2 \\ 2 & 0 & -2 & 0 & 0 \\ -2 & 2 & 0 & -3 & 0 \\ 2 & 0 & 3 & 0 & -2 \\ -2 & 0 & 0 & 2 & 0 \end{bmatrix}.$$ 

The point

$$q = \left( \frac{1}{8}, \frac{5}{16}, \frac{1}{8}, \frac{1}{8}, \frac{5}{16} \right),$$

is an equilibrium point of the replicator equation $X_{(A,n)}$. 
Figure: The pictures above represent the sets $\Delta_{\xi_1}, \ldots, \Delta_{\xi_5}$, where $\xi_1, \ldots, \xi_5$ are $\chi$-paths. The pictures below represent the $\pi_\xi$ iterates of $\Delta_{\xi_1}, \ldots, \Delta_{\xi_5}$, labelled from 1′ to 5′.
**Figure:** One orbit with 2000 iterates.
Let \( n = (2, 2, 2) \) and

\[
A = \begin{bmatrix}
0 & -5/2 & 0 & 9/8 & 0 & 2 \\
5/2 & 0 & 0 & -9/8 & -2 & 1 \\
0 & 0 & 0 & 0 & 1 & -2 \\
-5/4 & 5/4 & 0 & 0 & 0 & 0 \\
0 & 5/2 & -9/8 & 0 & 0 & -1 \\
-5/2 & -5/4 & 9/4 & 0 & 1 & 0
\end{bmatrix}.
\]

\( A = A_0 D \), where \( D = \text{diag} \left( \frac{5}{2}, \frac{5}{2}, \frac{9}{4}, \frac{9}{4}, 2, 2 \right) \) and
Asymptotic Poincaré Map

Hamiltonian Polymatrix replicators

Hamiltonian Asymptotic Poincare map

example

\[ A_0 = \begin{bmatrix}
0 & -1 & 0 & \frac{1}{2} & 0 & 1 \\
1 & 0 & 0 & -\frac{1}{2} & -1 & \frac{1}{2} \\
0 & 0 & 0 & \frac{1}{2} & -1 & 0 \\
-\frac{1}{2} & \frac{1}{2} & 0 & 0 & 0 & 0 \\
0 & 1 & -\frac{1}{2} & 0 & 0 & -\frac{1}{2} \\
-1 & -\frac{1}{2} & 1 & 0 & \frac{1}{2} & 0 \\
\end{bmatrix}, \]

\[ q = \left( \frac{7}{10}, \frac{3}{10}, \frac{5}{9}, \frac{4}{9}, \frac{1}{2}, \frac{1}{2} \right) \] is a formal equilibrium for \( A \). So \( (n, A) \) is conservative. The point \( q \) is inside \( \Gamma_n \) so it is an actual equilibrium point.
The phase space of the associated replicator system is the cube

$$\Gamma_{(2,2,2)} = \Delta^1 \times \Delta^1 \times \Delta^1 \equiv [0, 1]^3.$$
An other example where \( n = (3, 2) \) so
\[
\Gamma_{(3,2)} = \Delta^2 \times \Delta^1 \equiv \{ (x, y, z) : 0 \leq x, y, z \leq 1, \ x + y \leq 1 \}.
\]
We considered a system with a formal equilibrium outside \( \Gamma_n \).
